Abstract

In this paper we present three results concerning the unification problem in the description logic \mathcal{FL}_\perp . The logic \mathcal{FL}_\perp is a sub-Boolean logic that supports only conjunction, value restrictions, and the top and bottom constructors, without any form of negation. Subsumption in \mathcal{FL}_\perp can be decided in polynomial time. Although we do not solve the unification problem itself, we establish three related findings. First, we show that unification in \mathcal{FL}_\perp is of type nullary, a result inspired by a similar theorem for the modal logic K. Second, we reduce the unification problem in \mathcal{FL}_\perp to the unification problem in \mathcal{FL}_0 , equipped with a forward TBox. Third, we revisit the known result that the matching problem in \mathcal{FL}_\perp can be solved in polynomial time and provide a new algorithm for it.

Keywords

description logic, unification type

1. Introduction

In this paper, we focus on a small description logic, \mathcal{FL}_\perp , which extends the constructors of its sister logic \mathcal{FL}_0 by adding the bottom concept. We present three results: the unification type of \mathcal{FL}_\perp is nullary, inspired by a similar result for the modal logic K (see [1]); the unification problem in \mathcal{FL}_\perp can be reduced to the one in \mathcal{FL}_0 with a special TBox, corresponding to [2]; and we present a simple-to-implement algorithm which solves the matching problem in \mathcal{FL}_\perp in polynomial time.

2. The description logics \mathcal{FL}_0 and \mathcal{FL}_\perp

All notions in this chapter are introduced for \mathcal{FL}_\perp . To obtain their equivalents in \mathcal{FL}_0 , simply omit \perp . In the description logic \mathcal{FL}_\perp , (complex) concepts are generated from two disjoint sets N_C and N_R , referred to as concept names and role names, by the following grammar:
 $C ::= \top \mid \perp \mid A \mid C \sqcap C \mid \forall r.C$, where $A \in N_C, r \in N_R$.

 CEUR Workshop Proceedings (CEUR-WS.org)

An interpretation of concepts in \mathcal{FL}_\perp is a pair $I = (\Delta^I, \cdot^I)$, where Δ^I is a non-empty domain of elements and \cdot^I is an interpreting function defined on concept names and role names as follow: $\top^I = \Delta^I$; $\perp^I = \emptyset$; $A^I \subseteq \Delta^I$, for any $A \in N_C$; $r^I \subseteq \Delta^I \times \Delta^I$, for any $r \in N_R$, and extended to all complex concepts in the usual way: $(C \sqcap D)^I = C^I \cap D^I$; $(\forall r.C)^I = \{d \in \Delta^I \mid \forall e \in \Delta^I[(d, e) \in r^I \rightarrow e \in C^I]\}$; $(\forall v.C)^I = (\forall r_1 \forall r_2 \dots \forall r_n.C)^I$ where $v = r_1 \dots r_n \in N_R^+$.

A concept may be reduced with the following reductions to an equivalent concept (interpreted by the same set in any interpretation): $C \sqcap \top, \top \sqcap C \rightsquigarrow C$; $C \sqcap \perp, \perp \sqcap C \rightsquigarrow \perp$; $\forall r. \top \rightsquigarrow \top$; $\forall r.(C \sqcap D) \rightsquigarrow \forall r.C \sqcap \forall r.D$. We call a concept C *reduced* iff none of the reduction rules applies.

For convenience, we will use the notation $\forall v.\alpha$ for the concept of the form: $\forall r_1(\forall r_2(\dots(\forall r_n.\alpha)))$, where $v = r_1 \dots r_n$ and α is either \top or \perp or a concept name A . A concept of this form is called a *particle*. The word v over N_R is called *the role word of the particle* $\forall v.\alpha$. For role words v, v' , by $v \leq v'$ we denote that v is a prefix of v' .

It is easy to see that any concept is equivalent to a conjunction of particles, $C = \forall v_1.\alpha_1 \sqcap \dots \sqcap \forall v_n.\alpha_n$, where v_1, \dots, v_n are possibly empty words over N_R . In fact because of properties of conjunction, we identify a reduced concept with a set of particles in such a conjunction.

Let C be an \mathcal{FL}_\perp -reduced concept. We define $rd(C)$ (role depth) and $size(C)$ (size) recursively: if $C = A$ or $C = \top$ or $C = \perp$, then $rd(C) = size(C) = 0$; if $C = C \sqcap D$, then $rd(C) = \max\{rd(C), rd(D)\}$ and $size(C) = size(C) + size(D)$; if $C = \forall r.C'$, $rd(C) = rd(C') + 1$ and $size(C) = size(C') + 1$.

Subsumption between concepts $C \sqsubseteq D$ obtains iff for all interpretations I , $C^I \subseteq D^I$. *Equivalence*: $C \equiv D$ iff $C \sqsubseteq D$ and $D \sqsubseteq C$. For any concept C , we have $\perp \sqsubseteq C$ and $C \sqsubseteq \top$. In \mathcal{FL}_\perp , let C and $D = \{P_1, \dots, P_n\}$ be reduced concepts. Then $C \sqsubseteq D$ iff for every $P \in D$, one of the following holds: (1) $P \in C$, (2) $P = \forall v.\alpha$, where α is a concept name or \perp , and there exists $\forall v'.\perp \in C$ such that $v' \leq v$.

3. Unification problem in \mathcal{FL}_\perp

In order to define a unification problem, we partition the set of concept names N_C into two disjoint sets: variables (Var) and constants ($Cons$). A variable is thus a concept name that may be substituted by any concept while a constant cannot be substituted.

A *substitution* is a mapping from Var to the set of all \mathcal{FL}_\perp -concepts. It is extended to all concepts in the usual way. The *unification problem* (*unification problem*) is defined by its input $\Gamma = \{C_1 \sqsubseteq^? D_1, \dots, C_n \sqsubseteq^? D_n\}$; and the output is “yes” if there is a substitution that makes these subsumptions true, or “no” otherwise. Without loss of generality, we can assume that D_1, \dots, D_n are particles. A substitution σ is a *unifier* for the unification problem $\Gamma = \{C_1 \sqsubseteq^? P_1, \dots, C_n \sqsubseteq^? P_n\}$ iff $\sigma(C_1) \sqsubseteq \sigma(P_1), \dots, \sigma(C_n) \sqsubseteq \sigma(P_n)$. In this case, we say that the problem is *unifiable*.

Let Γ be an unification problem with the set of variables V and unifiers σ, γ . We say that σ is *more general* than γ (or γ is *less general* than σ), if there is a substitution τ such that $\gamma(X) \equiv \tau(\sigma(X))$, for all $X \in V$. If a unifier is more general than any other unifier, we call it a *most general unifier* (an mgu) of Γ .

A set Π of unifiers of a given unification problem Γ is called a *complete set of unifiers* if every unifier of Γ is less general than some element of Π . For a given unification problem Γ we define four *unification types* (from “best” to “worst”) based on the existence and cardinality of its complete set. The problem has unification type: *unitary* if there exists complete set of

unifiers consisting of one unifier σ ; *finitary* if it has finite complete set of unifiers, but has no most general unifier; *infinitary* if it has an infinite minimal complete set of unifiers; *nullary* (or *zero*) if it has no minimal complete set of unifiers. The unification type of a logic (\mathcal{FL}_\perp in our case) is the worst unification type of its unifiable problems.

4. Type nullary result

In this section, we sketch a prove that \mathcal{FL}_\perp has nullary unification type by showing that the unification problem $\Gamma = \{X \sqsubseteq^? \forall r.X\}$ has no minimal complete set of unifiers. To this end, we introduce the set U of substitutions consisting of:

$$\sigma_0(X) = \perp; \sigma_n(X) = X \sqcap \forall r.X \sqcap \dots \sqcap \forall r^{n-1}.X \sqcap \forall r^n.\perp, \text{ for } n \geq 1; \sigma_\top(X) = \top.$$

One can easily check that $\sigma_\alpha(X) \sqsubseteq \sigma_\alpha(\forall r.X)$, for each $\alpha \in \mathbb{N} \cup \{\top\}$.

It can also be shown that the set U is complete for Γ . Let σ be a unifier for Γ not equal to σ_\top and let $\sigma_n \in U$ where $n = rd(\sigma(X))$. Then $\sigma(X) \equiv \sigma(\sigma_n(X))$.

At this point we know that U is a complete set of unifiers of Γ . To complete the argument, we observe that there is no minimal complete set of unifiers for Γ . It can be easily shown that: σ_{n+1} is more general than σ_n , but σ_n is not more general than σ_{n+1} , for each $n \geq 0$. Using a proof by contradiction we obtain the result:

Theorem 1. *The type of the unification problem Γ is nullary.*

5. Reduction from \mathcal{FL}_\perp to \mathcal{FL}_0 with a TBox

A \mathcal{FL}_0 TBox (TBox for short) is a finite set of \mathcal{FL}_0 -subsumptions. A model of a TBox \mathcal{T} is an interpretation I such that $E^I \subseteq F^I$ for all $E \sqsubseteq F \in \mathcal{T}$. Let C and D be concepts. We say that C is subsumed by D w.r.t. a TBox \mathcal{T} (written $C \sqsubseteq_{\mathcal{T}} D$) if $C^I \subseteq D^I$ for each model I of \mathcal{T} . We say that σ is a unifier of a unification problem Γ w.r.t. a TBox \mathcal{T} if $\sigma(C) \sqsubseteq_{\mathcal{T}} \sigma(D)$ for each $C \sqsubseteq D \in \Gamma$.

Let C be an \mathcal{FL}_\perp concept, and B be a constant, that does not appear in C . By C_B we denote the \mathcal{FL}_0 -concept obtained from C by replacing all occurrences of \perp with the constant B . For $s = C \sqsubseteq D$, $s_B = C_B \sqsubseteq D_B$. Given a finite set Γ of \mathcal{FL}_\perp -subsumptions, we define the corresponding set Γ_B of \mathcal{FL}_0 -subsumptions by $\Gamma_B = \{s_B \mid s \in \Gamma\}$. For a given finite set of subsumptions Γ , $N_C(\Gamma)$ is the set of all concept names occurring in Γ , $N_R(\Gamma)$ is the set of all role names occurring in Γ . For a given signature $\Sigma = \langle S_C, S_R \rangle$, where S_C is a finite subset of N_C and S_R is a finite subset of N_R , we define the following TBox: $\mathcal{T}_B^\Sigma = \{B \sqsubseteq A \mid \text{for every } A \in S_C\} \cup \{B \sqsubseteq \forall r.B \mid \text{for every } r \in S_R\}$.

To simplify notation, we henceforth denote $\mathcal{T}_B^{\langle N_C(\{\perp\}), N_R(\{\perp\}) \rangle}$ as \mathcal{T}_B^s , and express $\langle N_C(\Gamma), N_R(\Gamma) \rangle$ as $\Sigma(\Gamma)$.

The following theorem is similar to Lemma 2.2 in [2], which considers subsumptions between concept names:

Theorem 2. *An \mathcal{FL}_\perp -subsumption s of the form $C \sqsubseteq D$ obtains iff $C_B \sqsubseteq_{\mathcal{T}_B^s} D_B$.*

If σ is a unifier of an \mathcal{FL}_\perp unification problem Γ of the minimal size where size of σ is sum of $\{size(\sigma(X)) \mid X \text{ is in domain of } \sigma\}$, then the signature of σ is contained in $\Sigma(\Gamma)$. Therefore:

Theorem 3. Let Γ be a unification problem in \mathcal{FL}_\perp . Then Γ has an \mathcal{FL}_\perp -unifier iff Γ_B has an \mathcal{FL}_0 -unifier w.r.t. the TBox $\mathcal{T}_B^{\Sigma(\Gamma)}$.

We showed that the unification problem in \mathcal{FL}_\perp can be reduced to a unification problem in \mathcal{FL}_0 with a TBox. This does not give us a solution for the unification in \mathcal{FL}_\perp , since unification in \mathcal{FL}_0 with a TBox is not solved. However, it shows that the unification problem in \mathcal{FL}_0 with a TBox is more difficult than unification in \mathcal{FL}_\perp .

6. Matching in \mathcal{FL}_\perp is polynomial

The matching problem is a special kind of a unification problem $C \equiv^? D$, where C contains no variables. In [3], it was shown that, with respect to general TBoxes, matching is ExpTime-complete in \mathcal{FL}_0 , whereas for a restricted form of TBoxes, namely *forward TBoxes*, the complexity drops to PSpace. We can transfer this result to \mathcal{FL}_\perp via Theorem 3, obtaining that matching in \mathcal{FL}_\perp is in PSpace. In [4] (see Theorem 3.8) it was shown that matching in \mathcal{FL}_\perp is polynomial. Here, we present another simple-to-implement algorithm which solves the matching problem in \mathcal{FL}_\perp in polynomial time.

Algorithm 1 Matching

Input: $C \equiv^? D$, where C does not contain variables, $D = E \sqcap \forall v_1.X_1 \sqcap \dots \sqcap \forall v_n.X_n$, where E does not contain variables, X_1, \dots, X_n are (not necessarily different) variables, and v_1, \dots, v_n are words over N_R .

Output: True if there is a matcher, False otherwise.

```

1: procedure MATCHING( $C \equiv^? D$ )
2:   if  $C \not\sqsubseteq E$  then
3:     return False
4:   else
5:     for all  $\forall v.A \in C$  such that  $\forall v.A \not\sqsubseteq E$  and there is no  $\forall v'.\perp \in E$  where  $v' \leq v$  do
6:       Find  $\forall v_i.X_i$  such that  $v_i \leq v$  ( $v_i$  is a prefix of  $v$ )
7:       if no  $\forall v_i.X_i$  is found then
8:         return False
9:   return True

```

One can see that the algorithm must terminate in time polynomial in the size of the problem. In order to justify the correctness of Algorithm 1 we define a special substitution $\hat{\sigma}$. For every X occurring in D , $\hat{\sigma}(X) := \sqcap \{ \forall u.\alpha \mid \forall v.X \in D \text{ and } \forall vu.\alpha \in C \text{ where } \alpha \text{ is a constant or } \perp \}$. Next we prove that a matching problem $C \equiv^? D$ has a unifier iff the substitution $\hat{\sigma}$ is a unifier. The correctness follows from the fact that the algorithm computes the substitution $\hat{\sigma}$.

7. Conclusions

We have presented three results related to the unification problem in \mathcal{FL}_\perp . The unification type of \mathcal{FL}_\perp turns out to be nullary. Hence, \mathcal{FL}_\perp has the same type as the description logics \mathcal{EL} , \mathcal{FL}_0 , and \mathcal{ALC} . The second result, reduction of the unification problem in \mathcal{FL}_\perp to unification in \mathcal{FL}_0 modulo a TBox \mathcal{T}_B^Σ implies that the unification problem in \mathcal{FL}_\perp is easier than the one in \mathcal{FL}_0 with a TBox. It is even easier than the unification in \mathcal{FL}_0 with a forward TBox. As the third result, we have presented a simple algorithm that solves matching in polynomial time.
